

## Agata Digitiser Fiber Optic connections test

This test is to verify that the fiber modules are powered ok by the power supply board.

1. Power on the digitiser with the default vhdl code (not samwise).
2. Power on DL fiber test Board set-up
3. Connect fiber cable 202658A to core module and 202659A to segment module.
4. Open com port in MIDAS, connect and press Push Button 3 on the DL fiber test Board (see com port screenshot below).

```

```

5. In order to sync, open the agata digitizer control web page, probe hardware and then “Setup Current Digitiser”. If successful, then we get the message as shown below. Sometimes the sync pulse is not transmitted correctly and this step report an error. In this case reprogram the DL fiber test Board set-up.

6. Looking back at the COM port then in status we should get “X000” and the data should be zero or close to it (above and below zero , see snapshot below).

Port: COM1 | Baud rate: 9600 | Data bits: 8 | Parity: none | Stop bits: 1 | Flow: none

Finish | Connect | Disconnect | Clear log window

```

7. Repeat for the rest of the segment module by plugging the fiber cable to the module under test, then “Resync Current Digitiser” from the control webpage and finally viewing the COM port.
8. For testing the core fiber move the 2 diff pairs from the segment fiber module to the core fiber module, resync and check the com port. Only channel 1 and 2 are relevant.
